

ORGANIC INTELLIGENCE PROTOCOL (OIP)

VERSION 1.0.30

CONSTRUCT MEASUREMENT & DATASET QUALIFICATION PROTOCOL

Evidence-First • Fail-Closed • Source-Locked • Pre-Specified

Lead Architect: Sudharsan Das
Location: Tripura, India
Predecessor: OIP v1.0.29 Evidence Audit Release
Source Specification: OIP v1.0.26 (January 2026)
Document Type: Normative Protocol
Primary Scope: Construct Measurement and Dataset Qualification

Publication Boundary

OIP v1.0.30 does not itself establish empirical validity, predictive validity, causal validity, universal validity, or real-world superiority of OIP.

It defines the evidentiary conditions under which a future empirical evaluation may be authorized.

This protocol must be source-locked against the authoritative OIP v1.0.26 specification before final archival freeze.

1 Purpose and Scope

OIP v1.0.30 establishes a pre-specified protocol governing the measurement of OIP constructs and the qualification of datasets for future empirical evaluation.

The protocol exists between:

- the dataset-specific evidence audit performed under OIP v1.0.29; and
- any future empirical evaluation release, such as OIP v1.0.31.

The purpose of this protocol is to determine, before confirmatory evaluation:

1. what constitutes sufficient evidence for construct measurement;
2. whether a candidate dataset variable is semantically admissible;
3. whether coding and routing are correctly understood;
4. whether missingness can be interpreted without fabrication;
5. whether temporal ordering is valid;
6. whether an outcome is independently observed and estimable;
7. whether leakage has been adequately controlled;
8. whether an analytical cohort can be frozen;
9. whether a future empirical evaluation may be authorized.

This document is therefore a **measurement and qualification protocol**, not an empirical results paper.

2 Scientific Status and Boundary

2.1 What this document establishes

This protocol establishes a set of rules for deciding whether evidence is sufficient to authorize an operationalization or future evaluation.

2.2 What this document does not establish

Completion of this protocol does **not** establish:

- empirical proof of OIP;
- predictive validity of OIP;
- causal validity of OIP;
- universal validity of OIP;
- superiority over competing frameworks;
- commercial validation;
- field effectiveness.

These claims require evidence from future authorized analyses and must never be inferred merely from protocol completion.

3 Authority and Evidence Hierarchy

3.1 Authoritative source

The theoretical definitions used in this protocol originate from the authoritative OIP v1.0.26 specification supplied for this release.

Where later documents contain interpretations, examples, candidate mappings, or implementation suggestions that are not explicitly supported by the authoritative source, those elements do not override the source.

3.2 Evidence hierarchy

The canonical hierarchy is:

1. OIP documented specification;
2. authoritative dataset codebook;
3. authoritative questionnaire and study documentation;
4. frozen raw data and provenance;
5. verified variable identity;
6. verified coding and category meaning;
7. routing and eligibility evidence;
8. missingness provenance and meaning;
9. construct semantic alignment;
10. directionality justification;
11. frozen operationalization;
12. frozen final analytical cohort;
13. frozen score calculation;
14. outcome estimability;
15. independent evaluation;
16. uncertainty analysis;
17. evidence-bounded claim.

3.3 Role of AI systems

AI-generated suggestions are **candidate hypotheses only**.

An AI system may:

- identify a possible variable;
- suggest a possible interpretation;
- identify a possible inconsistency;
- propose a review question.

An AI system may not, by itself:

- authorize a variable;
- define the meaning of a dataset field;
- invent a transformation;
- invent a missingness rule;
- establish construct validity;
- establish empirical validity.

4 Non-Negotiable Scientific Rules

The following rules are mandatory.

1. Variable existence does not imply construct validity.
2. Variable-name similarity or keyword matching does not establish semantic alignment.
3. Correct numerical coding does not establish construct validity.
4. Eligibility for one construct does not establish eligibility for the complete OIP expression.
5. Structural panel overlap is not equivalent to final analytical cohort membership.
6. Outcome availability is not equivalent to outcome estimability.
7. Score computability is not equivalent to empirical validation.
8. Fail-closed behavior is not itself proof that OIP is valid.
9. Missing values must not be silently converted to zero.
10. Missing outcomes must not be converted into negative outcomes without authoritative evidence.
11. Duplicates must not be silently removed solely for convenience.
12. No post-hoc feature, formula, threshold, or weight tuning is permitted after evaluation results are observed.
13. No universal claim may be inferred from a dataset-specific result.
14. No causal claim may be inferred from predictive or correlational evaluation alone.

5 Source-Locked OIP Construct Definitions

This section preserves the relevant definitions contained in the supplied OIP v1.0.26 specification.

The protocol does not replace the theoretical definitions with dataset-derived definitions.

5.1 Grounded Feedback Loop (GFL)

Source terminology:

“GFL (Grounded Feedback Loop): Real-world outcome correction.”

The detailed source definition states:

“Purpose: Ensure intelligence remains connected to real-world consequences.”

“Definition: $GFL = f(\text{RealWorld_Outcome_Error_Correction_Rate})$.”

“GFL Strength = Frequency of direct feedback $\times$ Speed of behavioral update.”

“If decisions cannot be tested against physical outcomes, GFL weakens.”

“If Outcome Feedback = 0 $\rightarrow$ System enters Static Mode $\rightarrow$ Reduce Decision Confidence.”

Protocol consequence:

A candidate dataset variable can represent GFL only where authoritative dataset evidence demonstrates compatibility with the source concept of real-world outcome feedback and correction.

An item that merely records:

- income source;
- geography;
- a static demographic attribute;
- a generic coping behavior;
- a single activity;

does not become GFL merely because it is numerically convenient.

5.2 Infrastructure Independence (II)

The source defines:

$$II = 1 - IDS.$$

The source states that II measures the ability to function without external technological systems and that:

$$IDS \in [0, 1].$$

The source gives the boundary interpretation:

$$IDS \rightarrow 1 \implies II \rightarrow 0,$$

and

$$IDS \rightarrow 0 \implies II \rightarrow 1.$$

5.3 Infrastructure Dependency Score (IDS)

The source defines IDS as:

“Degree to which reasoning requires external systems.”

The source also specifies the range:

$$0 \leq IDS \leq 1.$$

The source interpretation is:

- $IDS = 0$: fully independent;
- $IDS = 1$: fully dependent.

Protocol consequence:

A geographic variable is not automatically an IDS measure.

For example, village/urban location may correlate with infrastructure access, but correlation alone does not establish that the field measures *infrastructure dependency*.

An IDS operationalization therefore requires documentary evidence concerning the dependency concept itself.

5.4 Adaptive Moral Logic (AML)

The source defines AML as:

“AML (Adaptive Moral Logic): Life-preserving prioritization.”

The detailed source definition states:

“Purpose: Prioritize life-preserving and ecosystem-stabilizing outcomes over prestige, profit, or abstract efficiency.”

“Definition: $AML = f(\text{Life Preservation Weight} - \text{Prestige Optimization Weight})$.”

“If Action increases System Survival Probability AND decreases Resource Collapse Risk THEN Moral Priority = HIGH.”

“Prestige, institutional alignment, or short-term gain cannot override survival impact.”

Protocol consequence:

A generic coping-strategy variable does not automatically measure AML.

A candidate AML measure requires evidence that its semantics represent the life-preserving and/or ecosystem-stabilizing decision priority specified by the source.

6 Mathematical Scope

6.1 OIP Stability

The authoritative source defines:

$$OIP\ Stability = GFL \times II \times AML.$$

Because:

$$II = 1 - IDS,$$

the expression may be written as:

$$OIP\ Stability = GFL \times (1 - IDS) \times AML.$$

This is the primary mathematical pathway considered by the future empirical evaluation protocol when all three corresponding constructs can be legitimately operationalized.

6.2 Living Intelligence Value (LIV)

The source defines:

$$LIV = \frac{RI \times SR \times AR}{IDS}.$$

The source associates the variables with:

- *RI*: Resilience Impact;
- *SR*: Scalability Range;
- *AR*: Adaptation Rate;
- *IDS*: Infrastructure Dependency Score.

6.3 IDS boundary for LIV

Because *IDS* is the denominator:

$$IDS = 0 \implies LIV = \text{UNDEFINED}$$

This rule applies specifically to the LIV expression.

It does **not** justify removing *IDS* = 0 from the OIP Stability expression, because:

$$OIP\ Stability = GFL(1 - IDS)AML$$

is not undefined merely because *IDS* = 0.

Therefore:

Expression	IDS = 0	Protocol interpretation
$II = 1 - IDS$	Defined	Potentially valid
$GFL(1 - IDS)AML$	Defined if other terms are defined	Potentially evaluable
$LIV = (RI\ SR\ AR)/IDS$	Undefined	Not computable

Critical rule:

No workaround such as ϵ , denominator replacement, clipping, or arbitrary lower bounds may be introduced for LIV without an explicit authoritative specification.

7 Source-Document Formula Integrity

The supplied OIP v1.0.26 text contains multiple formula presentations.

For example, an early summary line presents:

$$Score = (0.6 \times Time \times Variable \times Stability),$$

while the later review-ready specification presents:

$$Score = (0.6 \times OE) + (0.3 \times CV) + (0.1 \times Verifiable_Impact_Stability).$$

Likewise, the early Formula 2 summary omits a term that is explicitly present in the later review-ready SIS formulation.

This protocol does **not** silently choose between contradictory source representations. Accordingly:

Any formula with multiple source representations must be explicitly version-locked before confirmatory implementation.

No analyst may select whichever form produces a more favorable result.

8 Survival Intelligence Score (SIS)

The source's later review-ready formulation defines:

$$SIS = (0.5 \times RC) + (0.3 \times AFL) + (0.2 \times Contextual\ Adaptation\ Speed).$$

This formula is distinct from:

$$OIP\ Stability = GFL(1 - IDS)AML.$$

The two expressions must not be combined into a new composite unless an authoritative OIP specification explicitly authorizes such a combination.

9 Stress-Response Weighting

The source proposes, under high-stress and low-infrastructure conditions:

$$IS = (SD \times 0.1) + (CW \times 0.9).$$

The source explicitly characterizes this as a *stress-response weighting model* and states that it is *not a universal constant*.

Therefore this model must not be silently converted into universal OIP weights for future empirical validation.

10 Measurement Qualification Requirements

A candidate variable mapping may be considered for approval only when the following evidence fields have been addressed.

Evidence layer	Requirement
Variable identity	Exact dataset field/column identity must be established.
Authoritative definition	The codebook, questionnaire, or study documentation must define the field.
Coding	Codes, labels, and direction must be verified from the source.
Routing	Eligibility and skip logic must be established where applicable.

Missingness	The meaning and provenance of missing values must be understood.
Semantic alignment	Evidence must show that the measure corresponds to the OIP construct itself.
Directionality	The relationship between the observed value and the construct must be justified.
Transformation	Any recoding, scaling, aggregation, reversal, or normalization must be pre-specified and evidence-supported.
Temporal validity	The variable must occur in the correct temporal relation to the outcome.
Reproducibility	Another analyst must be able to reconstruct the mapping from recorded evidence.

11 Operationalization State Machine

Each candidate operationalization shall use the following state progression:

NOT_ASSESSED → *EVIDENCE_FOUND* → *EVIDENCE_SUFFICIENT* → *APPROVED*.

Alternative states are:

EVIDENCE_INSUFFICIENT → *PENDING_EVIDENCE*,

and

CONTRADICTIONARY_EVIDENCE → *BLOCKED*.

The following principle applies:

PENDING_EVIDENCE is not failure of the theory. It is failure of the current evidence to authorize the operationalization.

12 Construct Approval Rule

A mapping is *APPROVED* only when all mandatory evidence fields have been satisfied.

Field	Required status
Variable identity	VERIFIED
Authoritative definition	VERIFIED
Coding	VERIFIED
Routing/eligibility	VERIFIED or supported N/A
Missingness provenance	VERIFIED
Semantic alignment	VERIFIED
Directionality	VERIFIED
Transformation	VERIFIED / PRE-SPECIFIED
Temporal validity	VERIFIED

If any mandatory field remains unresolved:

Operationalization Status = PENDING_EVIDENCE.

If authoritative evidence contradicts the proposed mapping:

Operationalization Status = BLOCKED.

No “best guess” approval is permitted.

13 Dataset Qualification Gates

A dataset may proceed to a future empirical evaluation only when all mandatory gates for the intended analysis are satisfied.

13.1 Gate 1 — Provenance and Integrity

Required:

- identifiable source;
- documented provenance;
- license/usage status recorded;
- immutable dataset hash;
- reproducible acquisition record.

Failure or unresolved evidence:

→ BLOCKED or PENDING_EVIDENCE

depending on whether the problem is disqualifying or resolvable.

13.2 Gate 2 — Temporal Validity

The dataset must establish the temporal direction required by the intended analysis.

A generic temporal structure may be represented as:

$$T_0 \rightarrow T_1 \rightarrow T_2.$$

Predictive variables must not be constructed using future information.

Post-outcome information cannot be treated as a valid pre-outcome predictor merely because it improves a metric.

Unverified temporal ordering:

→ PENDING_EVIDENCE.

13.3 Gate 3 — Construct Measurement Evidence

Every construct required for the intended OIP expression must have an approved operationalization.

For OIP Stability this means:

GFL, IDS, AML.

A dataset containing plausible proxy variables is not automatically qualified.

13.4 Gate 4 — Outcome Independence and Estimability

The outcome must be:

- externally observed;
- independently defined;
- temporally appropriate;
- available for the authorized analytical cohort.

For a binary evaluation such as ROC-AUC, both classes must be observed in the authorized evaluation cohort.

Formally, if:

$$N_{positive} > 0$$

and

$$N_{negative} > 0,$$

then binary class-based ROC-AUC may be estimable subject to the rest of the evaluation design.

If one class is absent:

$$ROC-AUC = \text{NOT_ESTIMABLE}.$$

This does **not** imply that the entire dataset is universally invalid. It means that the specified binary evaluation is not estimable under that observed cohort.

13.5 Gate 5 — No Synthetic Outcome Construction

No outcome may be manufactured from:

- OIP inputs;
- proxy variables;
- score components;
- heuristic labels;
- analyst-defined substitutions.

If the outcome is derived from the information used to construct the score, the intended independent evaluation is:

BLOCKED.

13.6 Gate 6 — Leakage Control

Leakage review must include, where applicable:

1. mechanical leakage;
2. temporal leakage;
3. semantic leakage.

Mechanical leakage includes exact or near-exact duplication of the outcome.

Temporal leakage includes future information entering predictor construction.

Semantic leakage includes variables that encode the target or the process by which the target was determined.

Correlation screening is useful but is not a complete semantic leakage audit.

14 Missingness and Routing Rules

Missingness shall be treated as an observed state, not an inconvenience to be eliminated.

The governing rule is:

$$\boxed{\text{Missing} \neq 0}$$

unless authoritative documentation explicitly proves that missingness denotes a substantive zero.

The protocol prohibits:

- silent $NaN \rightarrow 0$ conversion;
- synthetic negative outcomes;
- convenience deletion of records;
- arbitrary imputation;
- treating routed-out respondents as substantive zeros.

Routing-induced missingness must be distinguished from substantive missingness and from eligibility exclusion.

15 Analytical Cohort Formation

Structural linkage is not the final analytical cohort.

For a longitudinal analysis, the final cohort may be represented as:

$$C_{\text{final}} = C_{\text{linked}} \cap C_{\text{GFL}} \cap C_{\text{IDS}} \cap C_{\text{AML}} \cap C_{\text{outcome}} \cap C_{\text{temporal}} \cap C_{\text{nonmissing}} \cap C_{\text{other}}.$$

Every component must be evidence-supported before the cohort is frozen.

Therefore:

$$\boxed{\text{Structural overlap} \neq \text{Final analytical } N}$$

and:

Eligible for one construct $\neq$ Eligible for final OIP analysis

16 Dataset-Specific Rejection Examples

These examples illustrate the application of the source definitions.

They do not create new OIP definitions.

16.1 Candidate GFL Example

Suppose a dataset contains an item describing an income source.

That item may be perfectly real, correctly coded, and highly relevant to the study.

Nevertheless, it is not automatically GFL.

The source definition requires a relationship to:

RealWorld Outcome Feedback

and

Error Correction.

Therefore, absent authoritative semantic evidence establishing this relationship:

GFL operationalization = PENDING_EVIDENCE

or, where incompatible with the source definition,

GFL operationalization = BLOCKED.

16.2 Candidate IDS Example

Suppose a dataset contains a village/urban classification.

This is a geographic characteristic.

It may correlate with infrastructure access, but:

Geography $\neq$ *Infrastructure Dependency*

as a semantic identity.

Therefore an urban/rural field cannot be approved as IDS solely because urban settings tend to have greater infrastructure availability.

16.3 Candidate AML Example

Suppose a dataset contains a coping-strategy item.

Coping may be related to resilience, but:

Coping Strategy $\neq$ *Adaptive Moral Logic*

unless authoritative documentation establishes the required life-preserving and ecosystem-stabilizing decision-priority semantics.

17 Three Separate Scientific Gates

The protocol deliberately separates three questions.

17.1 Gate A — Score Computability

Question:

Can the frozen OIP expression be calculated using approved construct operationalizations and a frozen analytical cohort?

Passing Gate A means only:

Computable.

It does not mean:

Validated.

17.2 Gate B — Outcome Evaluation

Question:

Can the frozen score be evaluated against an independently observed, temporally valid, statistically estimable outcome?

For binary ROC-AUC:

$$N_{positive} > 0 \quad \wedge \quad N_{negative} > 0$$

is required.

17.3 Gate C — Empirical Validity Claim

Question:

Do the independent evaluation results, uncertainty analysis, leakage audit, and pre-specified claim boundary support the specific scientific claim?

Passing Gate C requires evidence.

It cannot be inferred from:

Gate A

or:

Gate B.

18 Pre-Specification and Freeze Rules

Before confirmatory empirical evaluation begins, the following must be frozen:

1. source definitions;
2. construct mappings;
3. inclusion/exclusion rules;
4. missingness rules;
5. temporal rules;
6. score weights;
7. transformations;
8. outcome definition;
9. evaluation metric(s);
10. evaluation design;
11. baseline specification, if applicable;
12. uncertainty/resampling procedure.

Once evaluation results are observed:

No post-hoc change may be represented as part of the original frozen test.

Any substantive modification requires a new protocol version or clearly separated exploratory analysis.

19 Baseline and Model Comparison Rule

A baseline is not automatically selected because it is available.

The protocol prohibits:

- selecting the first convenient numeric column as a baseline;
- selecting a baseline after seeing OIP performance;
- changing the baseline because the original comparison is unfavorable.

A baseline may be used only when its role and selection rule are pre-specified and scientifically defensible.

20 Uncertainty and Resampling

Uncertainty analysis must follow the analytical structure.

Resampling procedures, including bootstrap procedures, must not assume independent observations without evidence supporting that assumption.

For clustered, household, repeated-measures, or panel data, the resampling unit must be justified before execution.

No bootstrap result may be used to disguise an invalid or non-estimable evaluation design.

21 Leakage Audit Standard

Leakage review shall be performed independently of final performance.

The minimum conceptual audit is:

$$Leakage = Mechanical \vee Temporal \vee Semantic.$$

A system may not be declared leakage-free merely because no variable has a correlation greater than a chosen numerical threshold.

A semantic inspection remains required.

22 Future Dataset Qualification Principle

Dataset selection for confirmatory evaluation shall occur **after** measurement requirements are frozen.

The correct sequence is:

OIP source definitions → measurement criteria → dataset qualification → cohort freeze → evaluation.

The protocol therefore prohibits:

dataset first → construct definition later.

This ordering reduces confirmation bias and prevents the measurement rule from being redesigned around whichever dataset happens to produce favorable results.

23 Authorization Rule for OIP v1.0.31

A future empirical evaluation release may be authorized only when:

Source Definitions Frozen
 $\wedge$ GFL Approved
 $\wedge$ IDS Approved
 $\wedge$ AML Approved
 $\wedge$ Analytical Cohort Frozen
 $\wedge$ Score Frozen
 $\wedge$ Outcome Independent
 $\wedge$ Outcome Estimable
 $\wedge$ Leakage Audit Passed
 $\wedge$ Evaluation Design Frozen.

If one required condition remains unresolved:

→ PENDING__EVIDENCE.

If contradictory or disqualifying evidence exists:

→ BLOCKED.

24 Reproducibility Package

A future empirical evaluation release should contain, at minimum:

- frozen protocol;
- executable analysis notebook/code;
- environment specification;
- dataset provenance;
- immutable hashes;
- schema/data dictionary;
- operationalization registry;
- coding verification record;
- routing/eligibility record;
- missingness audit;
- leakage audit;
- frozen cohort definition;
- frozen score calculation;
- outcome definition;
- evaluation configuration;
- uncertainty configuration;
- final audit manifest.

25 Claim Discipline

The following statements are **not authorized** merely because v1.0.30 has been completed:

- “OIP is proven.”
- “OIP is scientifically proven.”
- “OIP is universally valid.”
- “OIP is causally validated.”
- “OIP has been universally validated.”
- “A successful audit proves OIP works.”
- “A high AUC proves OIP.”

A protocol-level statement that is authorized is:

OIP v1.0.30 defines a source-locked, evidence-first, fail-closed protocol for construct measurement and dataset qualification prior to empirical evaluation.

A future empirical claim must be limited to the evidence actually obtained.

26 Version Boundary

26.1 OIP v1.0.29

OIP v1.0.29 remains the frozen dataset-specific evidence-audit baseline.

Its documented audit findings are not retroactively altered by this protocol.

26.2 OIP v1.0.30

OIP v1.0.30 defines the normative measurement and dataset-qualification rules that govern future empirical evaluation.

It is not a results release.

26.3 OIP v1.0.31

OIP v1.0.31 is a future conditional empirical evaluation release.

It may proceed only if the authorization requirements of this protocol are satisfied.

27 Final Scientific Principle

The central rule of this protocol is:

Evidence must authorize the measurement; the measurement must authorize the score; the score must precede the evaluation; and the evaluation must precede the claim.

Therefore:

No evidence $\Rightarrow$ No operationalization

No approved operationalization $\Rightarrow$ No authorized score
--

No estimable outcome $\Rightarrow$ No authorized binary evaluation
--

No independent evaluation $\Rightarrow$ No empirical validity claim

Publication and Freeze Checklist

Before final archival publication of this protocol, verify:

1. The authoritative OIP v1.0.26 source is archived and identifiable.
2. GFL wording matches the authoritative source.

3. IDS wording and the 0–1 range match the authoritative source.

4. AML wording matches the authoritative source.

5. $II = 1 - IDS$ is preserved.

6. OIP Stability is preserved as:

$$GFL(1 - IDS)AML.$$

7. LIV is preserved as:

$$\frac{RI \times SR \times AR}{IDS}.$$

8. $IDS = 0 \Rightarrow LIV = \text{UNDEFINED}$ is preserved.

9. $IDS = 0$ is not incorrectly excluded from OIP Stability.

10. No BEMP-specific candidate is presented as universally valid.

11. No unsupported measurement scale has been added.

12. No synthetic outcome rule has been introduced.

13. No silent imputation rule has been introduced.

14. No post-hoc tuning rule has been introduced.

15. Binary evaluation is separated from construct qualification.

16. Score computation is separated from empirical validation.

17. The document makes no universal or causal validity claim.

18. Formula notation conflicts in the source are explicitly acknowledged rather than silently reconciled.

Protocol Status

OIP v1.0.30

CONSTRUCT MEASUREMENT & DATASET QUALIFICATION PROTOCOL

Status: SOURCE-LOCKED DRAFT FOR FINAL VERIFICATION

Scientific boundary: PRE-EVALUATION PROTOCOL

Empirical validity claim: NOT AUTHORIZED BY THIS DOCUMENT
