

Organic Intelligence Protocol

(OIP) v1.0.31

Fail-Closed Empirical Evaluation Audit

No evidence, no operationalization.

This report documents an evidence-first audit in which analytical execution remains conditional on the evidence required by the defined constructs.

Audit scope

This report documents the v1.0.31 computational audit conducted against the Malawi Integrated Household Panel Survey (IHPS) 2010–2019 longitudinal dataset. The audit examined dataset provenance, variable identity, coding, missingness, longitudinal identifier evidence, construct candidates, outcome candidates, and the conditions required for analytical execution.

Author	Sudharsan Das
Document type	Technical Audit Report
Version	v1.0.31
Audit date	September 11, 2026
Audit status	FAIL_CLOSED_AUDIT_COMPLETE
Empirical validation	NOT_ESTABLISHED

Claim boundary

This report does not establish predictive validity, causal validity, universal validity, superiority, commercial validation, field effectiveness, production readiness, hardware validation, or general AI alignment effectiveness.

The report records the evidence available to the audit and the decisions that followed from that evidence.

Primary executable audit record

Kaggle: [OIP v1.0.31 Fail-Closed Empirical Audit](#)

Executive Summary

The Organic Intelligence Protocol (OIP) v1.0.31 is documented as an evidence-first methodology for evaluating whether defined decision and intelligence constructs can be operationalized without introducing unsupported assumptions into the analytical process.

The v1.0.31 computational audit was conducted against the Malawi Integrated Household Panel Survey (IHPS) 2010–2019 dataset.

The computational pipeline successfully processed 395 Stata data files. It examined provenance, variable identity, coding, missingness, longitudinal identifier evidence, construct candidates, outcome candidates, and the conditions required for analytical execution.

The audit did not produce an empirical score.

The reason was methodological. The evidence required for construct operationalization and downstream execution was not sufficient.

Audit finding

The audit enforced its documented fail-closed conditions when required evidence was insufficient.

No unsupported proxy mappings were introduced. Missing values were not converted to zero. Unsupported imputation and random fallback logic were not used. Scoring was not performed before the required evidence gates were satisfied.

Final audit state

Audit status	FAIL_CLOSED_AUDIT_COMPLETE
GFL	PENDING_EVIDENCE
IDS	PENDING_EVIDENCE
AML	PENDING_EVIDENCE
Approved constructs	None
Longitudinal identifier	hh_b06_1
Identifier status	Approved for documented identifier use
Row-level longitudinal linkage	NOT_ESTABLISHED
Outcome approval	None
Analytical cohort	NOT_CREATED
Scores	NOT_PERFORMED
Empirical result	NOT_CLAIMED
Empirical validation	NOT_ESTABLISHED

The result is therefore an evidence-bounded audit finding. It should not be interpreted as either proof or disproof of OIP effectiveness.

1 What OIP Is

The Organic Intelligence Protocol is a structured methodology for determining whether a decision or intelligence system can be operationalized without allowing undocumented assumptions to enter the analytical pipeline.

The v1.0.31 approach uses a simple rule:

No evidence, no operationalization.

The rule separates what is observed from what is inferred.

A variable can exist in a dataset without measuring the intended construct.

A variable can have a documented code without providing sufficient evidence for the construct it is intended to represent.

An outcome variable can be available without being estimable for the required analytical cohort.

A mathematical expression can be calculated without constituting empirical validation.

For this reason the audit treats these conditions as separate evidence gates.

2 Core Constructs

2.1 GFL — Grounded Feedback Loop

GFL concerns feedback from real-world outcomes that can influence subsequent behaviour.

The documented OIP definition requires evidence of a feedback process rather than generic adaptation or coping behaviour.

2.2 IDS — Infrastructure Dependency Score

IDS concerns the degree to which reasoning depends on external systems under the documented OIP specification.

Infrastructure access by itself is therefore not treated as evidence of IDS.

2.3 Infrastructure Independence

Infrastructure Independence is defined as

$$II = 1 - IDS.$$

2.4 AML — Adaptive Moral Logic

AML concerns adaptive life-preserving prioritization under the documented OIP specification.

Evidence of a life-preserving choice by itself does not establish the complete AML construct.

2.5 OIP Stability

Where the required constructs have been independently approved, the documented stability relation is

$$OIP\ Stability = GFL \times (1 - IDS) \times AML.$$

The v1.0.31 audit did not authorize this score for empirical execution because the required construct evidence gates were not satisfied.

3 The Audit Question

The audit was designed around a narrow methodological question

Can the documented OIP constructs be operationalized against the selected real-world longitudinal dataset without introducing unsupported assumptions?

This question is different from asking whether OIP is effective or whether it predicts or causes an outcome.

Those are separate empirical questions and require evidence that was not established by this audit.

4 Evidence-First Audit Architecture

The audit followed a staged evidence hierarchy.

1. OIP documented specification
2. Authoritative dataset documentation and codebook
3. Questionnaire and study documentation
4. Frozen raw data and provenance
5. Verified variable identity
6. Coding and category meaning
7. Routing and eligibility
8. Missingness provenance and meaning
9. Construct semantic alignment
10. Directionality
11. Frozen operationalization
12. Final analytical cohort
13. Frozen score calculation
14. Outcome estimability
15. Independent evaluation
16. Uncertainty and claim discipline

A later-stage operation was not authorized simply because an earlier-stage artifact existed.

Important distinctions

Variable existence is not construct validity.

Data availability is not outcome estimability.

Score computability is not empirical validation.

Fail-closed execution is not proof of effectiveness.

5 Fail-Closed Execution

The audit uses the following evidence states

NOT_ASSESSED → EVIDENCE_FOUND → EVIDENCE_SUFFICIENT → APPROVED

Insufficient evidence leads to

EVIDENCE_INSUFFICIENT → PENDING_EVIDENCE.

Contradictory evidence leads to

CONTRADICTIONARY_EVIDENCE → BLOCKED.

The purpose is to prevent uncertainty from being converted into a definitive analytical result.

Operational consequence

When a required evidence gate was not satisfied, downstream cohort construction and scoring were not authorized.

6 Empirical Dataset

The empirical audit targeted the Malawi Integrated Household Panel Survey, covering panel waves from 2010 through 2019.

Dataset

Integrated Household Panel Survey 2010–2013–2016–2019

Producer

National Statistical Office, Malawi

Dataset DOI

[10.48529/q5q1-2a34](https://doi.org/10.48529/q5q1-2a34)

Computational audit scope

395 Stata .dta files successfully processed

The file count was not treated as evidence of longitudinal comparability.

Documentary evidence and linkage requirements were assessed separately.

7 Computational Audit Scope

The audit examined

- dataset provenance and integrity information
- Stata schemas and variable identity
- coding and category definitions
- missingness behaviour and meaning
- longitudinal identifier candidates
- construct candidates for GFL, IDS, and AML
- candidate outcome variables
- cohort eligibility requirements
- downstream scoring authorization gates

Construct meaning was not inferred from variable names alone.

8 Longitudinal Identifier Evidence

The strongest longitudinal identifier candidate identified during the audit was

hh_b06_1

Documentary evidence supported its use as a previous-survey roster identifier in the relevant panel context.

The audit maintained a separate distinction between identifier evidence and row-level linkage.

Identifier approval is not the same as row-level longitudinal linkage.

The identifier was therefore approved for its documented longitudinal identifier role.

Actual row-level longitudinal linkage remained

NOT_ESTABLISHED.

Simple value overlap between survey waves was not treated as proof of household or person-level linkage.

9 GFL Evidence Result

The audit identified documentary evidence concerning household shocks and household responses intended to regain a previous welfare state.

The available evidence did not establish all components required by the documented OIP definition of GFL.

The audit did not establish sufficient evidence for

- direct feedback
- subsequent behavioural update
- repeated feedback cycles
- an estimable real-world error-correction rate

GFL decision: PENDING_EVIDENCE

The evidence was relevant but insufficient for frozen operationalization.

10 IDS Evidence Result

The audit identified infrastructure-related information, including household electricity and related infrastructure variables.

Infrastructure access was not treated as equivalent to the OIP-defined degree of reasoning dependency on external systems.

Where documentary information was incomplete or contradictory, the audit did not resolve the issue through inference.

IDS decision: PENDING_EVIDENCE

No unsupported proxy mapping was authorized.

11 AML Evidence Result

The audit identified documentary evidence concerning life-preserving prioritization, including household decisions involving food allocation and children.

The available evidence did not establish the complete adaptive and comparative weighting structure required by the documented AML definition.

The audit did not establish sufficient evidence for

- an operational life-preservation weight
- a corresponding prestige-optimization weight
- the complete adaptive logic required by the documented construct definition

AML decision: PENDING_EVIDENCE

Relevant evidence was identified, but construct operationalization remained blocked.

12 Outcome Evidence Gate

Candidate outcome variables were identified and examined.

The audit distinguished between

- outcome candidate availability
- outcome definition
- outcome estimability
- linkage to the analytical cohort
- independent outcome status

The presence of candidate outcome variables did not authorize empirical scoring.

Outcome decision	
Outcome candidates	Found
Documentary outcome evidence	Found
Outcome estimability	NOT_ESTABLISHED
Outcome approval	None
Outcome linkage to analytical cohort	NOT_ESTABLISHED

13 Final Audit State

Table 1: OIP v1.0.31 Final Audit State

Audit component	Final state
Computational files processed	395 Stata files
GFL	PENDING_EVIDENCE
IDS	PENDING_EVIDENCE
AML	PENDING_EVIDENCE
Approved constructs	None
Longitudinal identifier	hh_b06_1
Identifier status	Approved for documented identifier use
Row-level longitudinal linkage	NOT_ESTABLISHED
Outcome approval	None
Analytical cohort	NOT_CREATED
Scores	NOT_PERFORMED
Empirical result	NOT_CLAIMED
Empirical validation	NOT_ESTABLISHED
Final public claim status	FAIL_CLOSED_AUDIT_COMPLETE

14 Why the Pipeline Stopped

The pipeline stopped because downstream execution depended on evidence gates that were not satisfied.

This was a deliberate fail-closed decision.

The audit did not

- substitute a proxy construct
- convert missing values to zero
- apply unsupported imputation
- select variables after observing desired analytical behaviour
- create a synthetic outcome
- treat missing outcomes as negative outcomes
- treat identifier overlap as proof of longitudinal linkage
- create a score merely because the mathematical formula was computable

**Evidence stopped.
The pipeline stopped.**

15 What the Audit Established

The v1.0.31 audit established that

1. A reproducible computational audit pipeline was executed against a real longitudinal dataset.
2. 395 Stata files were successfully processed.
3. Documentary and computational evidence gates were examined separately.
4. Construct candidates were not automatically promoted to approved operational variables.
5. Longitudinal identifier evidence was separated from actual row-level linkage.
6. Outcome availability was separated from outcome estimability.
7. Downstream analytical execution remained blocked when required evidence was insufficient.
8. The documented fail-closed rules were enforced during the audit.

16 What the Audit Did Not Establish

This report does not establish

- predictive validity
- causal validity
- universal validity
- superiority over other methods
- commercial validation
- field effectiveness
- production readiness
- hardware validation
- general AI alignment effectiveness

Evidence-bounded conclusion

The available evidence did not satisfy the gates required for empirical execution of OIP v1.0.31.

No empirical validation claim is therefore made.

17 Claim Discipline

The central methodological commitment of this research is to maintain a clear boundary between evidence and claim.

A technically computable result is not automatically an empirically defensible result.

The audit therefore uses explicit states such as

- APPROVED
- PENDING_EVIDENCE
- BLOCKED
- NOT_ESTABLISHED
- NOT_CREATED
- NOT_PERFORMED
- NOT_CLAIMED

The purpose is to make uncertainty visible rather than hide it behind a numerical output.

18 Reproducibility and Public Audit Trail

The primary executable computational audit record is publicly preserved on Kaggle.

Primary executable audit record

Kaggle — OIP v1.0.31 Fail-Closed Empirical Audit

The associated version-controlled repository provides the public research lineage, documentation, and versioned specification.

These records allow readers to inspect the methodology and independently reproduce or evaluate the computational audit where the underlying data and documentation permit.

19 Research Lineage

OIP v1.0.31 is part of an iterative methodological lineage.

Table 2: High-Level OIP Research Lineage	
Version	Role in the research lineage
v1.0.26	Initial architecture and formal concepts.
v1.0.27	Mathematical provenance, operationalization gaps, and completion register.
v1.0.28	Synthetic simulation and decision-logic demonstration. It was not treated as independent empirical validation.
v1.0.29	BEMP fail-closed empirical audit with insufficient construct documentation.
v1.0.30	Normative evidence hierarchy, operationalization gates, and claim discipline.
v1.0.31	Conditional empirical evaluation audit against Malawi IHPS longitudinal data.

20 Next Research Stage

The next stage is not additional scoring under the current evidence gap.

The appropriate next step is independent evidence review and, where justified, external evaluation.

A possible progression is

Independent Review → Construct Evidence → Frozen Operationalization → Independent Evaluation → Replication

Stronger empirical claims would require evidence from those later stages.

Current research position

The v1.0.31 audit is complete as an evidence-gated audit.

Further empirical execution remains conditional on obtaining the evidence required by the documented gates.

Closing Statement

The most important result was not a score.

The audit did not create a score when the evidence required for responsible operationalization was insufficient.

No evidence, no operationalization.
